Design Example Report

Title | 18.4 W Non-Dimmable, High Efficiency (>90%), Power Factor Corrected Non-Isolated Boost LED Driver Using LYTSwitch™-5 LYT5225D

Specification | 195 VAC – 265 VAC Input; 385 V, 48 mA Output

Application | Flood Lamp

Author | Applications Engineering Department

Document Number | DER-543

Date | April 18, 2016

Revision | 1.0

Summary and Features
- Single-stage power factor corrected, PF >0.9
- Accurate constant current regulation, ±5%
- Meets <10% flicker requirement
- Highly energy efficient, >90% at 230 V
- Low cost and low component count for compact PCB solution
- Integrated protection features
  - No-load output protection
  - Thermal fold-back protection
  - Over temperature protection
  - No damage during line brown-out or brown-in conditions
- Meets IEC 2.5 kV ring wave, 1 kV differential surge
- Meets EN55015 conducted EMI
PATENT INFORMATION
The products and applications illustrated herein (including transformer construction and circuits external to the products) may be covered by one or more U.S. and foreign patents, or potentially by pending U.S. and foreign patent applications assigned to Power Integrations. A complete list of Power Integrations' patents may be found at www.powerint.com. Power Integrations grants its customers a license under certain patent rights as set forth at <http://www.powerint.com/ip.htm>.

**Important Note:** Although this board is designed to satisfy safety isolation requirements, the engineering prototype has not been agency approved. Therefore, all testing should be performed using an isolation transformer to provide the AC input to the prototype board.
1 Introduction

This engineering report describes a non-dimmable, boost LED driver designed to drive a 385 V LED voltage string at 48 mA from an input voltage range of 195 VAC to 265 VAC. The LED driver utilizes the LYT5225D from the LYTSwitch-5 family of devices.

LYTSwitch-5 is a non-dimmable LED driver IC with single-stage PFC function and accurate LED current control. LYTSwitch-5 incorporates a high-voltage power MOSFET and discontinuous mode, variable frequency, variable on-time controller. The controller also provides fast (cycle-by-cycle) current limit, input and output OVP, plus advanced thermal management circuitry.

DER-543 provides a 48 mA accurate output current with a very low ripple (low % flicker) at 385 V LED output. The key design goals were high efficiency, accurate constant current regulation, low components count and low output ripple current.

The document contains the power supply specification, schematic, bill of materials, transformer documentation, printed circuit layout, design spreadsheet, and performance data.

3 Schematic

![Schematic Diagram]

Figure 4 - Schematic.
4 **Circuit Description**

The LYTSwitch-5 device (U1-LYT5225D) combines a high-voltage power MOSFET and a power supply controller in a single SO-16 package. For high efficiency solution, a smaller device (LYT5225D) was selected from LYTSwitch-5 output power table instead of larger device. LYT5225D is configured to drive a 385 V output non-isolated boost LED driver with 48 mA constant current output. An active ripple current filter circuit was added to provide lower output ripple current which correlates to a lower % flicker.

4.1 **Input Stage**

Fuse F1 provides safety protection from component failures. Varistor RV1 acts as a voltage clamp that limits the voltage spike on the primary during line transient voltage surge events. A 275 VAC rated part was selected, being slightly above the maximum specified operating voltage (265 VAC).

The AC input is full wave rectified by BR1 to achieve good power factor and low THD.

4.2 **EMI Filters**

The boost inductor T1 and L1 serve as differential choke. Inductor L1 together with the input filter capacitor C2 and C1 work as an EMI \( \pi \) filter. These EMI filters, together with the LYTSwitch-5 frequency jittering feature ensure compliance with the EN55015 Class B emission limit. Since differential choke L1 and boost inductor T1 are mutually connected in series due to their close proximity, L1 start polarity has great effect on EMI. If L1 is connected incorrectly, the mutual inductance effect would reduce the total series inductance of L1 and T1 and increases EMI. See below correct orientation.

![Figure 5 - L1 Marking and Position.](image-url)
4.3 **LYTSwitch-5 Primary Control Circuit**

The LED driver circuit is a boost topology. The primary winding finish terminal (no dot end) of the inductor (T1) is connected to the positive DC bus and the start (dotted end) terminal to the DRAIN (D) pin of the LYTSwitch-5 IC. During the on-time of the power MOSFET, current ramps through the primary winding, storing energy which is then delivered to the output load via output diode D1 during the power MOSFET off-time.

Capacitor C10 provides local decoupling for the BYPASS (BP) pin of U1, which is the supply pin for the IC. During start-up, the bypass capacitor C7 is charged to ~5.25 V from IC internal high-voltage current source connected to the D pin.

To provide input line voltage information to U1, the input AC voltage is sensed directly after the bridge rectifier diode through sampling resistors R2 and R3. The device input OVP function is activated when line sense current exceeds the OVP threshold. Output current regulation is achieved through direct output current sensing with respect to DRIVER CURRENT SENSE (DS) pin which is connected to SOURCE (S) pin through R10. With reference to the FEEDBACK (FB) pin threshold of 300 mV and DS, R14 senses the average output LED current directly from the output return rail. The sense resistor is connected before the output capacitor C4 for a faster feedback response enhanced by the output ripple current. Capacitor C10 provides voltage filtering across R14 for a more stable feedback. Resistor R11 and C7 set the desired time constant for optimized transient response. Diode D2 and D3 protects R14 and C12 from start-up transient voltage surge. It also prevents the triggering of the FB OVP function. The IC U1 OUTPUT COMPENSATION (OC) pin senses the output voltage directly through ROC resistors R5 and R8 for the output OVP function at open load. When the OC pin current exceeds the OV threshold, output OVP is activated with the IC latching off. This will prevent the output voltage from rising further. An AC recycle is needed to reset this protection mode once triggered. ROC resistor value should be set so as not to exceed the output capacitor rated surge voltage specification.

4.4 **Active Ripple Current Filter (ARF)**

Due to tight % flicker requirement on several applications, an active ripple current filter (ARF) is added to reduce the output ripple current. The ARF is almost similar to a linear series pass voltage regulator which comprises of NPN BJT (Q1) and an RC low pass filter (R4, R6 and C11). The low pass filter lowers the Q1 base drive current inducing a voltage drop across Q1 collector emitter. The voltage drop on Q1 CE reduces output ripple voltage, thereby reducing the output ripple current.

### 7.6 Transformer Winding Illustrations

#### Winding Directions

Bobbin is oriented on winder jig such that terminal pin 6-10 is in the left side. The winding direction is clockwise as shown in the figure.

#### Winding 1

Use wire item [3], start at pin 8 and wind 170 turns in 5 layers, then finish the winding on pin 10.

#### Insulation

Add 1 layer of tape, item [4], for insulation.
### Terminal Pins

Pull out terminal pins 1-7 and pin 9.

### Core Grinding

Grind the center leg of one core until it meets the nominal inductance of 780 $\mu$H.

### Core Assembly

Assemble the 2 cores on the bobbin with the ungapped core place on the terminal pin side as shown in the figure.

Wrap the 2 cores with polyester tape item (5). See figure on the right side.

### Bobbin Tape

Add 1 layer tape, Item (4), around the bobbin together with the core.

### Finish

Dip the transformer assembly in 2:1 thinner and varnish solution.
8 Performance Data

All measurements were performed at room temperature using LED loads string. 1 minute soak time was applied before measurement with AC source turned-off for 5 seconds every succeeding input line measurement.

10 Thermal Performance

10.1 Thermal Performance Scan - Open Frame Unit

Unit in open frame was placed inside the acrylic enclosure to prevent airflow that might affect the thermal measurements. Temperature was measured using FLIR thermal camera.

Figure 15 - Test Set-up Picture - Open Frame.
10.1.1 Thermal Scan

**Figure 16** - 230 VAC, 385 V LED Load.  
Spot 1: LYT5225D (U1): 72.5 ºC.

### 14 Line Surge

The unit was subjected to ±2500 V, 100 kHz ring wave and ±1000 V differential surge using 10 strikes at each condition. A test failure was defined as a non-recoverable interruption of output requiring repair or recycling of input voltage.
